

Where the truncating-variant effect emerges along the progression

Odds ratio for each gene at two adequately powered stages (log scale). Filled = FDR $q < 0.05$.

Firth's penalised logistic regression, adjusted for age and study; 95% profile-likelihood CIs.
ATM and CHEK2 are null at the benign stage and only reach significance at DCIS; BRCA2 is elevated at both.
BBD histological subtypes and LCIS rest on 0-3 carriers (unstable) and are not plotted.
